## Abstract

The KM3NeT research infrastructure in the deep Mediterranean Sea will host a multi-cubic-kilometre neutrino telescope and provide connectivity for continuous, long-term earth and sea science measurements. The KM3NeT neutrino telescope will complement the IceCube telescope at the South Pole in its field of view and surpass it substantially in sensitivity. In this document the major aspects of the KM3NeT technical design are described and the expected physics sensitivity is discussed. Finally, the expected time line towards construction is presented.

*Keywords:* Neutrino astronomy, KM3NeT, design study, Cherenkov detector

---

## 1. Introduction

Observing high-energy cosmic neutrinos opens fascinating opportunities to complement the information gained through electromagnetic radiation. Neutrinos are not absorbed nor deflected on the way from their source to the Earth, they can escape dense environments, and they are inevitably produced in regions where nuclei are accelerated to the energies typical for cosmic rays.

Neutrino telescopes are designed to observe the Cherenkov light emitted by secondary particles produced in neutrino reactions in transparent target media, such as water or ice. The first generation of such detectors, AMANDA at the South Pole [1], ANTARES in the Mediterranean Sea [2] and Baikal [3] in the homonymous Siberian lake, have proven the feasibility of this concept, albeit with instrumented volumes “only” of the order of a percent of a cubic kilometre.

Over the last decade, it has become obvious that km<sup>3</sup>-sized detectors are necessary to exploit the scientific potential of neutrino astronomy. A first detector of this size, IceCube [4], is currently being installed at the South Pole. The KM3NeT neutrino telescope [5] is to surpass IceCube in sensitivity by a substantial factor and complement it in its field of view. In particular, it will cover the Galactic Centre and a large fraction of

the Galactic plane that are hardly visible to IceCube and that contain prime candidates for neutrino emission in the high-energy regime [6].

Technical solutions for the KM3NeT neutrino telescope that are cost-effective, reliable, can be constructed in a reasonably short period and provide the targeted sensitivity have recently been presented in a Technical Design Report (TDR) [7]. For selecting and optimising these solutions, physics priorities had to be defined. For KM3NeT, the prime science objective is the detection and investigation of point-like sources of neutrino emission in the energy range 1–100 TeV, i.e. “classical” neutrino astronomy.

In the following, the KM3NeT technical design will be described (Sect. 2), physics sensitivity and cost discussed (Sect. 3) and the envisaged project time-lines presented (Sect. 4). This article is an update of [8]; further details can be found there and in [7, 9].

## 2. Technical Solutions

The neutrino telescope will be an array of optical modules, i.e. photomultiplier tubes (PMTs) in pressure-resistant glass spheres, attached to vertical structures (detection units, DUs). The DUs are anchored on the sea floor and kept vertical by subtended buoys. They are connected to shore via a sea-bottom network of electro-optical cables and junction boxes.

Experience from the first-generation Mediterranean projects, ANTARES, NEMO [10] and NESTOR [11],

---

<sup>☆</sup>Supported through the KM3NeT Design Study under EU FP6 contract no. 011937 and the KM3NeT Preparatory Phase project, FP7 grant no. 212525

54 shows that local clusters of PMTs are essential for event  
 55 selection and reconstruction due to the presence of opti-  
 56 cal background from K40 decays and bioluminescence.  
 57 Such clusters, mounted on mechanical frames called  
 58 storeys, can either comprise several optical modules  
 59 with one large PMT each, or one optical module with  
 60 multiple smaller PMTs (see Sect. 2.1).

61 For the DU structure, three design options are currently  
 62 investigated (see Sect. 2.2). They have in common  
 63 that the DUs can be folded into compact structures  
 64 for deployment and unfurl under water once they have  
 65 been placed on the sea floor. The main difference is the  
 66 horizontal distance between PMTs on the same DU.

67 The PMT signals will be processed by dedicated  
 68 front-end electronics recording time-over-threshold in-  
 69 formation for each signal (see Sect. 2.3).

### 70 2.1. Optical Modules

71 The classical optical module [12, 13] consists of a  
 72 pressure-resistant glass sphere (17 inch diameter) hous-  
 73 ing a large hemispherical PMT (10 inch) including its  
 74 high-voltage base, a mu-metal magnetic shielding, a  
 75 valve for pressure regulation during assembly and a  
 76 feed-through for a bulkhead connector.

77 In addition to simplified variants of this setup, featur-  
 78 ing 8-inch PMTs with increased quantum efficiencies in  
 79 13-inch spheres, a multi-PMT approach is being stud-  
 80 ied. In this multi-PMT module, 31 PMTs with 3 inch  
 81 diameter are fit into one 17-inch glass sphere, which also  
 82 contains the front-end electronics (see Fig. 1). High-  
 83 voltage bases with a power consumption as low as  
 84 140 mW for a complete optical module have been de-  
 85 signed for this application. The PMTs cover the direc-  
 86 tions of view from vertically downwards to about 45°  
 87 upwards. They are supported by a foam structure and  
 88 fixed to the glass sphere by optical gel. The overall pho-  
 89 to cathode area in one such optical module exceeds that  
 90 of a single-PMT one by more than a factor of three; a  
 91 further increase is possible by extending the light col-  
 92 lection area using reflective rings. The multi-PMT de-  
 93 sign provides very good separation between single- and  
 94 multiple-photon hits and some information on the pho-  
 95 ton direction.

### 96 2.2. Detection Unit

97 Three different approaches are currently being pur-  
 98 sued for the mechanical design of the DUs.

99 The *flexible tower* consists of an anchor unit and 20  
 100 horizontal bars of about 6 m length at vertical distances  
 101 of 40 m. Adjacent bars are connected by a tetrahedral  
 102 set of ropes, so that they are oriented orthogonally to

Figure 1: Schematic drawing of a multi-PMT optical module. In addition to the PMTs including their bases (D), an aluminium cooling structure (A) and the front-end electronic components (B,C) are indicated. A single penetrator is used to provide connectivity to the backbone cable.

103 each other. Each bar can carry three pairs of single-  
 104 PMT optical modules, one at each end and one in the  
 105 middle. Alternatively the bars could also be equipped  
 106 with 2 multi-PMT optical modules, one at each end. In  
 107 Fig. 2 the basic elements of the flexible tower in the con-  
 108 figuration with single-PMT optical modules are shown.

109 A full-size mechanical prototype similar to the setup  
 110 in Fig. 2 has been successfully deployed and unfurled in  
 111 February 2010.

112 Alternative to the flexible tower, *slender strings* are  
 113 considered. They are equipped with 20 multi-PMT opti-  
 114 cal modules at vertical distances of 30 m, fixed to two  
 115 parallel Dyneema® ropes. For deployment, the strings  
 116 are rolled onto spherical structures with a diameter of  
 117 about two metres. After lowering them to the sea bed,  
 118 they unroll under their buoyancy, thereby releasing the  
 119 string. This procedure has been successfully tested in  
 120 situ with a full-size prototype at the end of 2009.

121 A further alternative are *strings with extended storeys*,  
 122 each carrying three pairs of single-PMT OMs, arranged  
 123 in a triangular way on a circular mechanical frame.  
 124 The use of three multi-PMT optical modules per storey  
 125 would also be possible. One string carries 21 storeys  
 126 with vertical distances of 40 m. The general design prin-  
 127 ciple in this approach is based on the ANTARES ex-  
 128 perience and reduces the number of new components  
 129 and required tests. The storeys are interconnected by a  
 130 mechanical-electro-optical cable providing both electri-  
 131 cal power and fibre-optic data connectivity and mechan-  
 132 ical support.

Figure 2: Left: Schematic view of four storeys (thick black lines) and the ropes holding them in place (thin red lines); top right: Design of one of the storeys, with three pairs of optical modules; bottom right: Compactified tower ready for deployment, with the buoy on top.

133 Various considerations are common amongst differ-  
 134 ent design options:

135 A *backbone cable* along the DUs has been designed  
 136 for power and data transport, with the target to reduce  
 137 the numbers of penetrators and connectors (which are  
 138 expensive and failure-prone) and to implement a topol-  
 139 ogy without major single-point failures. This cable con-  
 140 sists of a oil-filled hose with copper conductors and op-  
 141 tical fibres inside, operated at equi-pressure with the  
 142 ambient sea water. At each storey, a break-out unit pro-  
 143 vides connectivity to one fibre and two copper conduc-  
 144 tors. The optical network is set up in a star-like topol-  
 145 ogy branching off an optical multiplexer located rough-  
 146 ly in the middle of a DU. A prototype of this backbone design  
 147 has been successfully tested; further verification steps  
 148 are under way. If successful, this concept is usable both  
 149 for the flexible towers and the slender strings. If not,  
 150 fall-back solutions using classical cables are available.

151 Regular position and orientation *calibration* is nec-  
 152 essary to account for the movement of the DUs in the  
 153 sea current. As in ANTARES, acoustic triangulation  
 154 methods will be applied, together with orientation mea-  
 155 surements by compasses and tilt-meters. The option to  
 156 glue the acoustic sensors to the inner surface of the opti-  
 157 cal modules is under study. For time calibration, pulsed  
 158 light signals from LED or laser beacons will be used.

### 2.3. Readout Scheme

159 A dedicated ASIC, the Scott chip, will be the central  
 160 front-end component of the readout. It converts the ana-  
 161 logue PMT signal into digital time-over-threshold infor-  
 162 mation, where one or several adjustable thresholds can  
 163 be assigned to each PMT. See Fig. 3 for a schematic  
 164 presentation of this functionality.

165 For use with single-PMT optical modules, the signal  
 166 shape can be reconstructed from the time-over-threshold  
 167 data for several thresholds per PMT. For the multi-  
 168 PMT configuration, one threshold will be assigned to  
 169 each PMT. At low rates, this allows for photon count-  
 170 ing by determining the number of PMTs hit in a cer-  
 171 tain coincidence window. At large rates, the time-over-  
 172 threshold information provides a logarithmic measure  
 173 for the number of photo-electrons per PMT.

174 All digitised data corresponding to PMT hits above a  
 175 noise threshold of typically 0.3 photo-electrons are sent  
 176 to shore and subjected to an online filter running on a  
 177 computer farm (about 1000 nodes) in the shore station.  
 178 Selected data are stored and distributed for analysis.  
 179

Figure 3: Functionality of the readout scheme. Top: A given PMT analogue signal is compared to a number of adjustable thresholds; middle: The comparator provides one on/off voltage signal per threshold; bottom: These signals are sampled at fixed time steps and the times over thresholds recorded in digital format.

### 2.4. Deep-Sea Infrastructure

180 The deep-sea cable network consists of one or few  
 181 main electro-optical cables from shore to primary junc-  
 182 tion boxes, from where it branches via secondary junc-  
 183 tion boxes to the DUs. Since the footprint of the detec-  
 184 tor is not yet decided, the exact configuration of the net-  
 185 work is still open. Both star-like topologies and a ring  
 186

187 topology of the main cable with branches to a series of  
 188 primary junction boxes are considered. The functional-  
 189 ities of cables, connectors and junction boxes in terms  
 190 of electrical power distribution and data transmission  
 191 have been studied in detail and are well defined. They  
 192 will be implemented based on the existing experience  
 193 from ANTARES, NEMO and other deep-sea research  
 194 projects such as NEPTUNE [14]. The overall power  
 195 consumption will be about 125 kW, the overall data rate  
 196 sent to shore will be of the order 25 GByte/s.

### 197 3. Physics Sensitivity and Cost

198 Detailed Monte Carlo simulations have been per-  
 199 formed for the design options discussed above, taking  
 200 into account signal, atmospheric neutrino and atmo-  
 201 spheric muon events. It turns out that optimal solutions  
 202 for event and hit selection, reconstruction and definition  
 203 of quality cuts strongly depend on the PMT arrange-  
 204 ment; in particular, single- and multi-PMT optical mod-  
 205 ules require significantly different approaches. The cor-  
 206 responding optimisation process has not yet fully con-  
 207 cluded, so that the results reported here have remaining  
 208 uncertainties and, at the same time, are conservative.

209 Simulation studies have been central in optimising  
 210 design parameters, in particular with regard to the de-  
 211 tector geometry. Based on these studies, detector con-  
 212 figurations using the DU design options described in  
 213 Sect. 2.2 have been defined for further simulation and  
 214 for cost estimation purposes. For the flexible towers and  
 215 the extended strings, these are equilateral hexagons of  
 216 127 DUs arranged on a regular triangular grid, with an  
 217 inter-DU distance of 180 m (flexible towers) or 150 m  
 218 (extended strings), respectively. For the slender strings,  
 219 a homogeneous configuration of 310 DUs at distances  
 220 of 130 m was chosen. A driving objective behind these  
 221 choices was to define units of approximately equal sen-  
 222 sitivity that could be implemented using one main cable  
 223 to shore. The simulations indicate that these configura-  
 224 tions are very similar in sensitivity, in particular when  
 225 applying strict quality cuts.

226 The investment cost for the three detector configura-  
 227 tions discussed above has been estimated based on  
 228 commercial quotations, experience from existing instal-  
 229 lations, price lists and input from marine science and  
 230 technology projects. The results, including costs for  
 231 the deep-sea network and the deployment but not for  
 232 the shore infrastructure or personnel, are 88, 107 and  
 233 99 M€ for the flexible towers, slender strings and ex-  
 234 tended strings, respectively. Please note that these num-  
 235 bers carry an uncertainty of at least 20% and thus do not  
 236 provide a basis for a quick technology decision.

Figure 4: Sensitivity of the full KM3NeT neutrino telescope to point-like sources of neutrino emission with fluxes proportional to  $E_\nu^{-2}$  as a function of declination  $\delta$  (red line extending to  $\delta = -90^\circ$ ). The sensitivity is inferred from a binned analysis of simulation data. The vertical axis indicates the expected exclusion limit at 90% C.L for 1 year of livetime. Also shown is the corresponding IceCube sensitivity (black dashed line at positive declinations, taken from [15]). The tick marks in the lower panel indicate the positions of TeV gamma sources in the Galactic plane, the blue star marks the Galactic Centre.

237 The configurations investigated fall short to reach the  
 238 objective of surpassing IceCube by a substantial factor  
 239 in sensitivity (see below). The full KM3NeT neutrino  
 240 telescope is therefore envisaged to comprise approx-  
 241 imately two of the configurations (“building blocks”)  
 242 discussed above, so as to be compatible with a projected  
 243 overall capital investment budget of 220 M€ [16, 17].  
 244 The operation costs for this set-up have been estimated  
 245 to be between 4 and 6 M€, depending on the number of  
 246 maintenance operations required. This corresponds to  
 247 2–3% of the capital investment and thus is significantly  
 248 lower than for other projects of comparable complexity.

249 The full KM3NeT neutrino telescope will instrument  
 250 a water volume of 4 to 5 cubic kilometres and thus by  
 251 far outperforms the initial target of the KM3NeT De-  
 252 sign Study, i.e. a price tag of 200 M€ per instrumented  
 253 km<sup>3</sup> of water. The sensitivity of the full KM3NeT de-  
 254 tector to point sources emitting a neutrino flux propor-  
 255 tional to  $E_\nu^{-2}$  is shown in Fig. 4 as a function of the  
 256 declination of the source. The shape of the sensitivity  
 257 curve reflects declination dependences of the visibility,  
 258 the effective area and the Earth’s transparency to neu-  
 259 trinos. Also indicated are the corresponding IceCube sen-  
 260 sitivity and the declinations of the TeV gamma sources  
 261 in the Galactic plane, which are prime candidates for  
 262 high-energy neutrino emission. The KM3NeT sensitiv-  
 263 ity is better than that of IceCube over a large fraction  
 264 of the full sky (about  $3.5\pi$  steradians), by more than half  
 265 an order of magnitude on average. There is room for

266 further improvement by optimising the event selection 304  
 267 and reconstruction procedures or using unbinned analy- 305  
 268 sis methods. 306

#### 269 4. Project Development

270 The projected KM3NeT time lines towards construc- 308  
 271 tion and operation are indicated in Fig. 5.

Figure 5: Time line of the KM3NeT project development towards construction and operation.

272 The further work will be organised inside the FP7-  
 273 funded KM3NeT Preparatory Phase project running un-  
 274 til February 2012. The decisions for specific techni-  
 275 cal solutions require further prototyping and field tests.  
 276 A period of 18 months after TDR publication (June  
 277 2010) is foreseen for these activities, as well as for  
 278 verifying those component designs which are new and  
 279 have been developed specifically for the KM3NeT neu-  
 280 trino telescope (such as the equi-pressure backbone, the  
 281 front-end electronics or the multi-PMT optical mod-  
 282 ules). Concurrently, simulation studies will be pursued  
 283 to react to technical developments and to assess the de-  
 284 tector footprint.

285 At the same time scale, a site decision has to be taken.  
 286 Currently, three sites (near Toulon, at the east coast of  
 287 Sicily and at the west coast of the Peloponnesus) have  
 288 been proposed. They differ in depth (2.5 km to 5 km),  
 289 in distance to shore (between about 15 km and 100 km)  
 290 and in their environmental properties.

291 Once these decisions have been taken, the final techni-  
 292 cal design of the KM3NeT Research Infrastructure will  
 293 be laid down in a detailed proposal. Assuming that  
 294 funding, legal and administrative issues are sorted out  
 295 by then, it will be possible to launch production at that  
 296 point.

297 Data taking will start as soon as the first DUs are op-  
 298 erational. From a very early stage of its construction  
 299 on, the data from the KM3NeT neutrino telescope will  
 300 exceed data from first-generation Northern-hemisphere  
 301 neutrino telescopes in quality and statistics and thus pro-  
 302 vide an exciting discovery potential.

303 **Acknowledgements:** The KM3NeT project is sup-

ported by the EU in FP6 under contract no. 011937 and  
 in FP7 under grant no. 212525. The author thanks the  
 RICH10 organisers for their hospitality and a very well  
 organised, inspiring conference.
